# Section 1: Introduction

## Overview

The New Zealand Health Survey (NZHS) is an important data collection tool, which is used to monitor population health and provide supporting evidence for health policy and strategy development. The Health and Disability Intelligence (HDI) group, within the Ministry of Health's (the Ministry's) Client Insights and Analytics business unit, is responsible for designing, analysing and reporting on the NZHS. The NZHS field activities are contracted out to a specialist survey provider, CBG Health Research Ltd.

The NZHS collects information that cannot be obtained more effectively or efficiently through other means, such as by analyses of hospital administrative records, disease registries or epidemiological research. For most topics in the NZHS, the survey is the best source of information at a population level.

Previous NZHSs were conducted in 1992/93, 1996/97, 2002/03 and 2006/07. In addition, separate stand-alone surveys on specific subjects have been conducted once every three or four years as part of the wider health survey programme. These surveys covered adult and child nutrition; tobacco, alcohol and drug use; mental health; and oral health. From July 2011, all the above surveys were integrated into the single NZHS, which is now in continuous operation.

From 2013 onwards, a number of key outputs from the NZHS became Tier 1 statistics (a portfolio of the most important official statistics, essential to understanding how well New Zealand is performing). For the 2015/16 year, the eight Tier 1 statistics from the NZHS are: smoking (current), past-year (alcohol) drinking, hazardous (alcohol) drinking, obesity, unmet need for a general practitioner (GP) due to cost, unfilled prescription due to cost, self-rated health and mental health status (psychological distress).

This NZHS methodology report outlines the procedures and protocols followed to ensure the NZHS produces the high-quality and robust data expected of official statistics (Statistics New Zealand 2007). The information specific to the current year 5 of the continuous NZHS (data collected between July 2015 and June 2016) is included in Section 9 of this report. The corresponding information for years 1, 2, 3 and 4 of the NZHS can be found in the previous methodology reports.<sup>1</sup>

<sup>1</sup> See [www.health.govt.nz/nz-health-statistics/national-collections-and-surveys/surveys/current-recent-surveys/new-zealand-health-survey](http://www.health.govt.nz/nz-health-statistics/national-collections-and-surveys/surveys/current-recent-surveys/new-zealand-health-survey)

# Background

As a signatory of the Protocols for Official Statistics (Statistics New Zealand 1998), the Ministry employs best-practice survey techniques to produce high-quality information through the NZHS. It uses standard frameworks and classifications, with validated questions where possible, so that NZHS data can be integrated with data from other sources.

The goal of the continuous NZHS is to support the formulation and evaluation of policy by providing timely, reliable and relevant health information. This information covers population health; health risk and protective factors; and health service utilisation.

To achieve this goal, a number of specific objectives have been identified. The *Content Guide 2015/16: New Zealand Health Survey* contains further information on these objectives (Ministry of Health 2016b).

The NZHS has been carefully designed to minimise the impact on survey respondents. Features for this purpose include:

- selecting only one eligible adult and one eligible child per dwelling
- using well-tested and well-proven questionnaires
- using professional, trained interviewers to conduct the interviews
- making an appointment to conduct each interview at a time that suits the respondent and their family
- having the option of using a proxy respondent where would-be respondents living in private dwellings have severe ill health or cognitive disability.

The New Zealand Health and Disability Multi-Region Ethics Committee granted approval for the NZHS (MEC/10/10/103) in 2011.

# Section 2: Survey content

The NZHS comprises a set of core questions combined with a flexible programme of rotating topic modules. The questionnaire is administered (face to face and computer assisted) to adults aged 15 years and older, as well as to children aged 0–14 years, generally through their primary caregiver, who acts as a proxy respondent.

Over previous years, the content of NZHSs has remained similar so that data can be compared over time. The current NZHS maintains continuity with the previous surveys by including a set of core questions in both the adult and child questionnaires. The module topics change every 12 months.

Cognitive testing is undertaken to ensure the questions are understood as intended and response options are appropriate.

For more detail on the rationale of topic inclusion, cognitive testing and the content of the questionnaires, see the *Content Guide 2015/16* (Ministry of Health 2016b).

## Core content

Most of the core questions for both adults and children are drawn from the main topic areas included in the 2006/07 NZHS and 2011/12 NZHS. Topic areas include long-term conditions, health status and development, health behaviours, health service utilisation and patient experience, sociodemographics, and anthropometry. Table 1 summarises the topics included in the core content of the NZHS.

**Table 1: Core content of the NZHS**

Topic area	Topics
<b>Children</b>	
Long-term conditions	Asthma, eczema, diabetes, rheumatic heart disease, mental health conditions
Health status and development	General health
Health behaviours	Breastfeeding, nutrition, physical activity, family cohesion
Health service utilisation and patient experience	Primary health care provider use, general practitioners, nurses, medical specialists, oral health care professionals, other health care professionals, hospital use, prescriptions
Sociodemographics	Child: sex, age, ethnicity, language, country of birth Primary caregiver/proxy respondent: relationship to child, age, education, income and income sources, employment status, and household characteristics
Anthropometry	Height, weight and waist circumference measurements

Topic area	Topics
<b>Adults</b>	
Long-term conditions (self-reported)	Heart disease, stroke, diabetes, asthma, arthritis, mental health conditions, chronic pain, high blood pressure, high blood cholesterol
Health status	General health (physical and mental health), psychological distress
Health behaviours	Physical activity, tobacco smoking, vegetable and fruit intake, alcohol use and hazardous drinking
Health service utilisation and patient experience	Primary health care provider use, general practitioners, nurses, medical specialists, oral health care professionals, other health care professionals, hospital use, prescriptions
Sociodemographics	Sex, age, ethnicity, language, country of birth, education, income and income sources, employment status, medical insurance, household characteristics
Anthropometry	Height, weight and waist circumference measurements; blood pressure

## Module component

All the module topics for the continuous NZHS until 2015/16 are summarised in Table 2.

**Table 2: NZHS module topics, 2011/12–2015/16**

Year of NZHS	Child module topic(s)	Adult module topic(s)
2011/12	Health service utilisation Patient experience	Health service utilisation Patient experience Problem gambling Discrimination
2012/13	Child development Food security Exposure to second-hand smoke	Alcohol use Tobacco use Drug use
2013/14	Long-term conditions Health status Disability status Living standards Housing quality	Long-term conditions Health status Disability status Living standards Housing quality
2014/15	Child development Rheumatic fever	Sexual and reproductive health Biomedical tests Rheumatic fever (under 25 years)
2015/16	Child development Child food security Rheumatic fever	Tobacco use Rheumatic fever (under 25 years)

---

# Section 3: Survey population and sample design

This section describes the target population, the survey population and the sample design for the NZHS.

## Target and survey population

The **target population** is the population the survey aims to represent. The **survey population** is the population that was covered in the survey.

### Target population

The target population for the NZHS is the New Zealand ‘usually resident’ population of all ages, including those living in non-private accommodation.

The target population is approximately 3.6 million adults (aged 15 years and over) and 0.9 million children (aged from birth to 14 years), according to the Statistics New Zealand Census population figures for 2013.

Previously (2006/07 and earlier), the NZHS included only people living in private accommodation. The target population for the current NZHS includes people living in non-private accommodation to improve coverage of older people in an ageing population.

### Survey population

Approximately 99 percent of the New Zealand usually resident population of all ages is eligible to participate in the NZHS. For practical reasons, a small proportion of the target population is excluded from the survey population. The following are excluded from the survey population:

- most types of non-private dwellings (prisons, hospitals, hospices, dementia care units and hospital-level care in aged-care facilities)
- households located on islands other than the North Island, South Island and Waiheke Island.

Included in the survey population are people living in aged-care facilities (rest homes) and those temporarily living away from their household in student accommodation (university hostels and boarding schools).

## Sample design

The sample design for the NZHS has been developed by the National Institute for Applied Statistics Research Australia (NIASRA), University of Wollongong, Australia.

The sample design used in the current year, year 5 or 2015/16, is slightly different from the sample design used in the previous four years. The main changes are listed below.

- The first-stage selection units are now Statistics New Zealand’s household surveys frame primary sampling units (PSUs) rather than census meshblocks used in the previous four

years. PSUs are groupings of one or more meshblocks. There have also been some associated changes to the selection probabilities and the number of dwellings selected from each PSU.

- PSUs are now selected using the Statistics New Zealand coordinated selection facility to manage overlap across many government surveys and to minimise the NZHS revisiting the same households.

For more detail on the new sample design of the current year 2015/16, see *Sample Design from 2015/16: New Zealand Health Survey* (Ministry of Health 2016d). For more details of the sample design of the previous years, see Clark et al (2013) and *The New Zealand Health Survey: Sample design, years 1–3 (2011–2013)* (Ministry of Health 2011).

## Sample selection

The NZHS has a multi-stage, stratified, probability-proportional-to-size (PPS) sampling design. The survey is designed to yield an annual sample size of approximately 14,000 adults and 5000 children.

A dual-frame approach has been used, whereby respondents are selected from an area-based sample and a list-based electoral roll sample. The aim of this approach is to increase the sample sizes for Māori, Pacific and Asian ethnic groups.

### Area-based sample

Statistics New Zealand's PSUs form the basis for the area-based sample. The area-based sample is targeted at the ethnic groups of interest by assigning higher probabilities of selection to areas (PSUs) in which these groups are more concentrated.

A three-stage selection process is used to achieve the area-based sample.

First, a sample of PSUs is selected within each district health board (DHB) area. The PSUs are selected with PPS, where the size measure is based on the counts of occupied dwellings from the 2013 Census. This means that larger PSUs have a higher chance of being selected in the sample. The size measures are modified using a targeting factor to give higher probabilities of selection to PSUs where more Pacific or Asian people live, again based on the 2013 Census.

Second, a list of households is compiled for each selected PSU. A systematic sample of approximately 21 households is selected from this list by choosing a random start and selecting every  $k^{\text{th}}$  household. The skip  $k$  is calculated by the census occupied-dwellings count divided by 21.

Third, one adult (aged 15 years or over) and one child (aged from birth to 14 years, if any in the household) are selected at random from each selected household.

Any aged-care facilities in the selected PSUs are included in the area-based sample by first dividing them into 'accommodation units', typically consisting of an individual or couple living together in the facility. Accommodation units are then treated as households in the sampling process, although at most, five accommodation units are selected from a single facility.

Students living away from home in university hostels and boarding schools are eligible to be selected via their family's house, if they still consider this to be their home. If selected, arrangements are made to survey them either when they are next at home or at their student accommodation.

## **Electoral roll sample**

The electoral roll is another sampling frame used to increase the sample size of the Māori ethnic group. The electoral roll is used to select a sample of addresses where a person has self-identified as having Māori ancestry. A copy of the electoral roll is obtained quarterly for this purpose.

Stratified three-stage sampling is used to select the sample from the electoral roll.

The first stage involves selecting a sample of PSUs within each stratum (DHB area), with probability proportional to the number of addresses on the electoral roll containing at least one person who has self-identified as having Māori ancestry. The sample of PSUs is selected so that it does not overlap with the sample of PSUs for the area-based sample.

The second stage involves selecting a systematic sample of 14 addresses (from the list of households where any person has self-identified as having Māori ancestry) from each selected PSU, or all addresses if there are fewer than 14 addresses in a selected PSU.

In the third stage, one adult (aged 15 years or over) and one child (aged from birth to 14 years, if any in the household) are selected at random from each selected address.

The electoral roll is used in order to increase the recruitment rate of Māori into the sample. However, the process of contacting households and selecting an adult and child is exactly the same as for the area-based sample. In particular, the adult and child (if any in the household) randomly selected into the survey can be Māori or non-Māori. This approach ensures that probabilities of selection can be correctly calculated for all respondents.

---

# Section 4: Data collection

Data for the NZHS are collected by CBG Health Research Ltd (CBG). The CBG interview team consists of approximately 35 professional social research interviewers.

Interviews are conducted in respondents' homes, with the interviewer entering responses directly into a laptop computer using The Survey System's Computer-Assisted Personal Interview (CAPI) software. 'Show-cards' with predetermined response categories are used to assist respondents, where appropriate.

## Pilot study

A pilot study was carried out with 100 respondents from seven PSUs in Paihia, Auckland, Tauranga and Porirua before the main data collection for the 2015/16 NZHS. The purpose of the pilot was to determine average survey timings for different groups and refine the survey instruments, materials, operations and processes to suit. No substantive changes were made following the 2015/16 pilot study.

## Enumeration

CBG identifies households from PSUs selected for the survey using the New Zealand Post address database, which is obtained quarterly. Each area PSU visited by an interviewer is re-enumerated in order to record new dwellings built and those removed since the last census enumeration and release of the New Zealand Post address list. The details of new dwellings are entered into CBG's Sample Manager software while the interviewer is in the field, allowing these households to be included in the random selection process for the PSU.

## Invitation to participate

The NZHS is voluntary, relying on the goodwill of respondents, and consent is obtained without coercion or inducement. CBG uses the New Zealand Post address database to post each selected household an invitation letter from the Ministry, along with an information pamphlet about the NZHS. Interviewers take copies of the information pamphlet in 11 languages when they subsequently visit households to seek people's agreement to participate in the survey.

One adult and one child (if any in the household) are randomly selected from each selected household to take part in the survey using CBG's Sample Manager software. Respondents are asked to sign an electronic consent form and are given a copy of the consent form to keep. The consent form requires the respondent to confirm that they have read and understood the information pamphlet and that they know they can ask questions at any time and can contact CBG or the Ministry for further information. The consent form also states that:

- the respondent can stop the interview at any time and they don't have to answer every question
- their participation is confidential and no identifiable information will be used in any reports
- their answers are protected by the Privacy Act 1993.

The consent form also includes a request for an interpreter, if required (in any of a range of different languages). The respondent may elect a friend or family member (aged 15 years or over) to act as the interpreter during the survey, or CBG will arrange a professional interpreter. Attempts are also made to match respondents and interviewers by ethnicity and sex when requested.

Where a selected adult respondent is unable to provide consent themselves, a legal guardian is permitted to consent and complete the survey on their behalf, if the legal guardian agrees to participate.

Child interviews are conducted with a guardian/primary caregiver of the child; that is, a person who has day-to-day responsibility for the care of the child.

All respondents for the NZHS are given a thank you card and a small token of appreciation, such as a pen or fridge magnet, at the conclusion of the interview. The thank you card contains a list of health and community organisations with freephone numbers that respondents can use if they would like to discuss any issues raised by their participation in the NZHS or if they need advice on a health issue.

## **Call pattern**

Interviewers make up to 10 calls to each sampled dwelling at different times of the day and on different days of the week before accepting that the dwelling is a non-contact. Calls are recorded as unique events only if they are made at least two hours apart.

The number of calls made by an interviewer is spaced over two to three months. Up to six calls are made by the interviewer during the month in which the PSU is first being surveyed. If contact with the household is not established during this first month, there is a pause for three to four weeks before attempting two more calls. If contact is still not established, there is another pause for a further three to four weeks before attempting a final two calls. This procedure helps to contact not only people who are temporarily away, but also those who are busy with work or family or socially when their dwelling is first approached.

## **Interviewer audits**

CBG conducts audit calls with around 10 percent of all respondents and at least one household per PSU. Respondents are also left with feedback postcards, which they can use to send feedback directly to CBG, anonymously if they choose.

## **Interviewer training**

Interviewers take part in ongoing training courses run by CBG on how to conduct interviews.

## **Objective measurements**

All respondents aged two years and over have their height and weight measurements taken by the interviewer at the end of the survey. Those aged five years and over also have their waist circumference measured. In addition, adults aged 15 years and over are asked to provide a blood pressure reading. Pregnant women are excluded from having any measurements taken.

In the 2012/13 NZHS, laser height measurement was introduced. The measuring device consists of a professional laser meter (Precaster HANS CA770) mounted to a rigid headboard, which the interviewer holds against the corner of a wall or door. The headboard is lowered until it reaches the respondent's head, at which point the laser is activated to take a measurement. The laser design was trialled and refined in early 2012 before it was used for the NZHS from July 2012. The laser meter replaced traditional stadiometers, which were used in the 2011/12 NZHS.

Weight is measured with electronic weighing scales (Tanita HD-351). Respondents are required to empty their pockets as well as remove their shoes and any bulky clothing that could produce an inaccurate reading.

Waist circumference is measured using an anthropometric measuring tape (Lufkin W606PM). The measurement is taken over one layer of clothing at the midpoint between the lowest palpable rib and the top of the hip bone.

Height, weight and waist circumference measurements are taken a minimum of twice each. If there is more than a 1 percent variation between the first and second measurements, then a third measurement is taken for accuracy. To align with international standards, the final height, weight and waist measurements used for analysis are calculated for each respondent by taking the mean of the two closest measurements.

Blood pressure measurement was introduced to the NZHS in July 2012 and is obtained using a portable electronic sphygmomanometer (Omron HEM 907). A fabric cuff is wrapped around the respondent's upper left arm, just above the elbow. Within the cuff is a plastic bladder connected by a tube to the main device. As the bladder inflates, the device is able to detect the respondent's blood pressure. The device is programmed to take three readings, with a 1-minute pause between each.

Respondents are left with a measurement card, which details the readings taken on the day of the survey. The card also provides information on interpreting the blood pressure measurement and where the respondent can go for further information or advice.

Several techniques are used to ensure the quality of the objective measurement equipment. Interviewers immediately report faulty equipment to CBG management and replacements are supplied immediately. Equipment is also checked by CBG management at least twice every year in the field.

Additionally the equipment is checked and re-calibrated at the time of the annual module change training, where:

- the electronic weighing scales and automatic blood pressure machines are re-calibrated by a manufacturer-approved agent
- the lasers are checked against a known fixed height to ensure they are measuring correctly and are still programmed to the correct settings.

Interviewers are retrained annually and must pass a re-certification assessment to ensure they maintain the required skill levels.

# Changes to alcohol consumption questions

To improve the accuracy of alcohol consumption reporting by adult respondents, a picture showcard was developed for the 2015/16 year that depicts the number of 'standard drinks' contained in a range of common alcoholic drinks and vessel sizes. The showcard is used for two questions (A3.26 and A3.27), which have historically been asked in the NZHS. The showcard questions now refer to 'standard drinks' rather than 'drinks', as used in the historical questions.

The showcard is left with respondents at the conclusion of the interview for their future reference.

See the NZHS 2015/16 adult questionnaire for the instructions given on the two relevant alcohol questions.

In order to assess the impact of introducing the standard drinks show-card, the adult sample in the 2015/16 survey was split into two groups. Half of the respondents were asked the questions in the same manner as previous years (sample group A), whilst the other half were asked the questions with the show-card (sample group B). Among the respondents interviewed by the same interviewer, CBG's Sample Manager software alternated between the two versions of the alcohol questions. This allows us to:

- produce population statistics of alcohol consumption from a half sample (sample group A) to compare with the statistics produced in previous years
- produce population statistics of alcohol consumption from the other half sample (sample group B) based on the new 'standard drinks' questions
- compare the population statistics of alcohol consumption of the two samples to examine the magnitude of the differences.

From 2016/17 onwards, the NZHS will only use the standard drinks showcard version of questions (A3.26a and A3.27a).

---

# Section 5: Response and coverage rates

The response rate is a measure of how many people who were selected to take part in the survey actually participated. A high response rate means that the survey results are more representative of the New Zealand population.

In 2015/16, the final weighted response rate was 80 percent for both adults and children. For more details on the response rates for 2015/16, see Section 9.

The response rate is an important measure of the quality of a survey. Methods used to maximise response rates include:

- giving interviewers initial and ongoing training and development
- supporting and assessing interviewers in the field
- using well-designed call pattern processes, allowing for up to 10 calls to potential respondents at different times of the week and day
- revisiting 'closed' PSUs during a mop-up phase (ie, when visiting households where no contact has been established or the selected respondent was unable to take part at that time but did not refuse to participate).

## Calculating the response rate

The NZHS calculates a weighted response rate. The weight of each household reflects the probability of the household being selected into the sample; thus the weighted response rate describes the success of the survey in terms of achieving the cooperation of the population being measured.

For adults, the response rate calculation classifies all selected households into the following four groups.

1. Ineligibles (eg, vacant sections, vacant dwellings and non-residential dwellings).
2. Eligible responding (interview conducted, respondent confirmed to be eligible for the survey).
3. Eligible non-responding (interview not conducted but enough information collected to indicate that the household did contain an eligible adult; almost all refusals were in this category).
4. Unknown eligibility (eg, non-contacts and refusals who provided insufficient information to determine eligibility).

The response rate is calculated as follows:

$$\text{Response rate} = \frac{\text{number of eligible responding}}{\left[ \begin{matrix} \text{number of eligible} \\ \text{responding} \end{matrix} \right] + \left[ \begin{matrix} \text{number of eligible} \\ \text{non-responding} \end{matrix} \right] + \left[ \begin{matrix} \text{estimated number of eligibles} \\ \text{from the unknowns} \end{matrix} \right]} \times 100$$

The justification for using this calculation method is that a proportion of the unknowns is likely to have been eligible if contact could have been made. This proportion of the unknowns is therefore treated as eligible non-responding.

The estimated number of unknown eligibles is calculated as follows:

$$\left[ \begin{matrix} \text{Estimated number} \\ \text{of eligibles from the} \\ \text{unknowns} \end{matrix} \right] = \left[ \begin{matrix} \text{number} \\ \text{of} \\ \text{unknowns} \end{matrix} \right] \times \frac{\left[ \begin{matrix} \text{number of eligible} \\ \text{responding} \end{matrix} \right] + \left[ \begin{matrix} \text{number of eligible} \\ \text{non-responding} \end{matrix} \right]}{\left[ \begin{matrix} \text{number of eligible} \\ \text{responding} \end{matrix} \right] + \left[ \begin{matrix} \text{number of eligible} \\ \text{non-responding} \end{matrix} \right] + \left[ \begin{matrix} \text{number of} \\ \text{ineligibles} \end{matrix} \right]}$$

The response rate for children is calculated using the same approach as for adults, but ‘eligible’ means the household contained at least one child and the definition of ‘responding’ is that a child interview was conducted.

## Coverage rate

The coverage rate is an alternative measure related to survey response and shows the extent to which a population has been involved in a survey. It provides information on the discrepancy between the responding sample (weighted by selection weight) and the population. It encompasses the impact of non-response rates but also incorporates other factors, such as being excluded or missed from the sample frame. For example, dwellings that have just been built may not be included in the sample frame, in this way contributing to under-coverage.

The coverage rate is defined as the ratio of the sum of the selection weights for the survey respondents to the known external population size.

Unlike the response rate, the coverage rate can be calculated without making any assumption about how many households with unknown eligibility were in fact eligible. Moreover, the coverage rate can usually be broken down in more detail than the response rate, including by individual characteristics. However, definitional or operational differences between the survey scope and the external population size (eg, differing definitions of usual residence) will affect the coverage rate. As a result, the response rate is generally used as the primary measure of the survey’s quality. Some information on the coverage rate is included here to provide more detail on response, particularly response by ethnicity and age group.

Coverage rates also represent the factor by which the calibrated weighting process adjusts the selection weights in order to force agreement with the calibration benchmarks (see Section 7 for more on calibration).

For details on the coverage rates in 2015/16, see Section 9.

---

# Section 6: Data processing

## Capturing and coding

Questionnaire responses are entered directly on interviewers' laptops using The Survey System's Computer-Assisted Personal Interview (CAPI) software.

Most questions have single-response options or require discrete numerical responses, such as age at the time of a specific event or the number of visits to a specific medical professional. However, a number of questions allow for multiple responses. For these questions, all responses are retained, with each response shown as a separate variable on the data file.

In addition, a number of questions in the questionnaire offer an 'other' category, where respondents can specify non-standard responses. Each 'other' category response is recorded (in free text).

Ethnicity is self-defined, and respondents are able to report their affiliation with more than one ethnic group using the Statistics New Zealand standard ethnicity question. Responses to the ethnicity question are coded to level 3 of the 2005 standard ethnicity classification.

## Securing information

Any information collected in the survey that could be used to identify individuals is treated as strictly confidential. Data are transferred daily from interviewers' laptops to CBG by a secure internet upload facility. The Ministry accesses the data through the CBG website using a secure log-in username and password.

The names and addresses of people and households that participate in the survey are not stored with response data. Unit record data are stored in a secure area and are only accessible on a restricted basis.

## Checking and editing

CBG and the Ministry both routinely check and edit the data throughout the field period of the NZHS. In addition, the final unit record data sets provided to the Ministry are edited for range and logic. Any inconsistencies found are remedied by returning to the interviewer and, if necessary, the respondent for clarification and correction.

## Missing data due to non-response

Unit non-response is where no response is obtained from the selected household or person; for example if the household is unable to be contacted or declines to participate. Item nonresponse is where the respondent does not provide an answer to some (but not all) questions asked on the questionnaire, usually because they don't know or refuse to answer.

Unit non-response is adjusted for in the calculation of weights, as described in Section 7. Weighting is also used to adjust for non-response to the measurement phase of the interview.

Almost all questions have less than 1 percent item non-responses. The questions with the most item non-responses are:

- personal income and household income (7.5 percent and 15.0 percent non-response respectively)
- questions that ask for the cost of the respondent's last GP or nurse visit (around 4–5 percent non-response).

Item non-response to the income questions was lower for the 2015/16 year compared with the respective figures of 10.3 percent and 20.0 percent reported in the previous year. In 2015/16, the questions on income were improved. A picture show-card was developed to make it easier for respondents to estimate their annual personal income by showing the weekly and fortnightly equivalent of each annual income band. Also, the number of response options (income bands) for household income was reduced to make it easier to answer the questions.

Where a respondent does not provide their date of birth or their age in years, age is imputed as the midpoint of the age group they have provided. No other imputation is used to deal with item non-responses.

## Creating derived variables

A number of derived variables are created on the NZHS data set. Many of the derived variables, such as body mass index (BMI), Alcohol Use Disorders Identification Test (AUDIT) and level of psychological distress (K10), are based on commonly used or standard definitions to enable comparison with other data sources and with other countries. Other derived variables, such as a summary indicator of physical activity level that incorporates information on the intensity, duration and frequency of physical activity, are developed specifically for the NZHS.

See the *Indicator Interpretation Guide 2015/16: New Zealand Health Survey* (Ministry of Health 2016c) for more detailed information on all the indicators used in the NZHS reports.

## Outliers

Respondents with height and weight measurements that lead to a calculated BMI of less than 10 or greater than 80 are treated as non-respondents to the measurement phase of the interview.

Respondents who report more than 112 hours of physical activity per week (an average of 16 hours per day) are excluded from the derived summary measure of physical activity.

## Ethnicity

Ethnic group variables are derived using the concept of **total response ethnicity** (Statistics New Zealand 2005). This means that respondents can appear in, and contribute to the published statistics for, more than one ethnic group.

NZHS reports generally provide statistics for the following four ethnic groups: Māori, Pacific peoples, Asian and European/Other. The 'Other' ethnic group (comprising mainly Middle-Eastern, Latin-American and African ethnicities) has been combined with European to avoid problems with small sample sizes.

Respondents who don't know or refuse to state their ethnicity are included as European/Other, as are those who answer 'New Zealander'.

## Neighbourhood deprivation

Neighbourhood deprivation refers to the New Zealand Index of Deprivation 2013 (NZDep2013), developed by researchers at the University of Otago (Atkinson et al 2014). NZDep2013 measures the level of socioeconomic deprivation for each neighbourhood (meshblock) according to a combination of the following 2013 Census variables: income, benefit receipt, transport (access to car), household crowding, home ownership, employment status, qualifications, support (sole-parent families) and access to a telephone.

NZHS reports generally use NZDep2013 quintiles, where quintile 1 represents the 20 percent of small areas with the lowest levels of deprivation (the least deprived areas) and quintile 5 represents the 20 percent of small areas with the highest level of deprivation (the most deprived areas).

A small number of meshblocks do not have a value for NZDep2013. If any of these meshblocks are selected in the NZHS, the respondents are assigned to quintile 3 (ie, the middle quintile) for weighting and analysis purposes.

---

# Section 7: Weighting

Weighting of survey data ensures the estimates calculated from these data are representative of the target population.

Most national surveys have complex sample designs whereby different groups have different chances of being selected in the survey. These complex designs are used for a variety of purposes, in particular to:

- reduce interviewer travel costs by ensuring the sample is geographically clustered
- ensure all regions of interest, including small regions, have a sufficient sample size for adequate estimates to be made
- ensure important sub-populations, in particular the Māori, Pacific and Asian ethnic groups, have a sufficient sample size for adequate estimates to be made.

To ensure no group is under- or over-represented in estimates from a survey, a method of calculating estimates that reflects the sample design must be used. Estimation weights are used to achieve this aim.

A weight is calculated for every respondent, and these weights are used in calculating estimates of population totals (counts), averages and proportions. Typically, members of groups that have a lower chance of selection are assigned a higher weight so that these groups are not under-represented in estimates. Conversely, groups with a higher chance of selection receive lower weights. Also, groups that have a lower response rate (eg, young men) are usually assigned a higher weight so that these groups are correctly represented in all estimates from the survey.

The NZHS uses the calibrated weighting method to:

- reflect the probabilities of selecting each respondent
- make use of external population benchmarks (typically based on the population census) to correct for any discrepancies between the sample and the population benchmarks; this improves the precision of estimates and reduces bias due to non-response.

Data from each calendar quarter of the NZHS data set are weighted separately to population benchmarks for that quarter. This means that each quarter's data can be used to produce valid population estimates.

## Calculating selection weights

The first step in producing calibrated weights is to calculate a selection probability (and hence selection weight) for each respondent. It is crucial to calculate selection weights correctly to avoid bias in the final calibrated estimators.

Selection weights for the area-based sample and the electoral roll sample are calculated in different ways.

## Area-based sample

- The probability of a PSU  $i$  being selected in the area-based sample (A) is written as  $\pi_{Ai}$ . The values of  $\pi_{Ai}$  are greater than 0 for all PSUs in the survey population.
- The probability of a dwelling being selected from a selected PSU  $i$  in the area sample is  $1/k_{Ai}$ , where  $k_{Ai}$  is a skip assigned to each PSU on the frame.
- The probability of any particular adult being selected from a selected dwelling  $j$  in a selected PSU  $i$  is then  $1/N_{ij(\text{adult})}$ , where  $N_{ij(\text{adult})}$  is the number of adults in the dwelling. Similarly, the probability of any particular child (if any in the household) being selected is  $1/N_{ij(\text{child})}$ , where  $N_{ij(\text{child})}$  is the number of children in the dwelling.

## Electoral roll sample

- The probability of a PSU  $i$  being selected in the electoral roll sample (R) is written as  $\pi_{Ri}$ . The values of  $\pi_{Ri}$  are 0 for some PSUs (those with fewer than three households with residents who registered Māori descent on the electoral roll snapshot used in the sample design for that year).
- Dwellings are eligible for selection in the electoral roll sample if they have at least one adult registered as being of Māori descent in the electoral roll snapshot extracted for the enumeration quarter. ( $E_{ij} = 1$  if PSU  $i$  has  $\pi_{Ri} > 0$  and dwelling  $j$  in this PSU is eligible;  $E_{ij} = 0$  otherwise.)
- A skip  $k_{Ri}$  is assigned to each PSU and applied to eligible dwellings. The probability of an eligible dwelling being selected from PSU  $i$  in the electoral roll sample is  $1/k_{Ri}$ , where  $k_{Ri}$  is a skip assigned to each PSU on the frame.
- The probability of any particular adult being selected in the electoral roll sample from a selected dwelling  $j$  in a selected PSU  $i$  is then  $1/N_{ij(\text{adult})}$ , and the probability of any particular child (if any in the household) being selected is  $1/N_{ij(\text{child})}$ .

## Combined sample

The electoral roll sample and the area-based sample are selected according to the probabilities calculated using the above methods. The two samples of PSUs do not overlap. The complete NZHS sample is defined as the union of the two samples. The probability of selecting any adult in dwelling  $j$  in PSU  $i$  in the combined sample is therefore:

$$(1) \quad \pi_{ij(\text{adult})} = E_{ij}\pi_{Ri}k_{Ri}^{-1}N_{ij(\text{adult})}^{-1} + \pi_{Ai}k_{Ai}^{-1}N_{ij(\text{adult})}^{-1} = (E_{ij}\pi_{Ri}k_{Ri}^{-1} + \pi_{Ai}k_{Ai}^{-1})N_{ij(\text{adult})}^{-1}$$

Similarly, the probability of selecting any child in dwelling  $j$  in PSU  $i$  in the combined sample is:

$$(2) \quad \pi_{ij(\text{child})} = E_{ij}\pi_{Ri}k_{Ri}^{-1}N_{ij(\text{child})}^{-1} + \pi_{Ai}k_{Ai}^{-1}N_{ij(\text{child})}^{-1} = (E_{ij}\pi_{Ri}k_{Ri}^{-1} + \pi_{Ai}k_{Ai}^{-1})N_{ij(\text{child})}^{-1}$$

The selection weights for adults and children are given by the reciprocal (inverse) of the above:

$$(3) \quad d_{ij(\text{adult})} = \pi_{ij(\text{adult})}^{-1} = (E_{ij}\pi_{Ri}k_{Ri}^{-1} + \pi_{Ai}k_{Ai}^{-1})^{-1} N_{ij(\text{adult})}$$

$$(4) \quad d_{ij(\text{child})} = \pi_{ij(\text{child})}^{-1} = (E_{ij}\pi_{Ri}k_{Ri}^{-1} + \pi_{Ai}k_{Ai}^{-1})^{-1} N_{ij(\text{child})}$$

# Calibration of selection weights

Calibrated weights are calculated by combining the selection weights and population benchmark information obtained externally from the survey. The NZHS uses counts from Statistics New Zealand's estimated resident population for each calendar quarter, broken down by age, sex, ethnicity and socioeconomic position, as its benchmark population.

Calibrated weights are calculated to achieve two requirements.

1. The weights should be close to the inverse of the probability of selecting each respondent.
2. The weights are calibrated to the known population counts for a range of sub-populations (eg, age-by-sex-by-ethnicity categories). This means that the sum of the weights for respondents in the sub-population must equal exactly the known benchmark for the sub-population size.

Requirement 1 ensures that estimates have low bias, while requirement 2 improves the precision of estimates and achieves consistency between the survey estimates and external benchmark information. The calibrated weights are calculated in such a way as to minimise a measure of the distance between the calibrated weights and the inverse selection probabilities, provided that requirement 2 above is satisfied.

A number of distance measures are in common use. A chi-square distance function (case 1 in Deville and Särndal 1992) is used for calibrating the NZHS weights, which corresponds to generalised regression estimation (also known as GREG). This distance function is slightly modified to force weights to lie within certain bounds, with the aim of avoiding extreme weights.

The inverse selection probability is sometimes called the initial weight. The final, calibrated weights are sometimes expressed as: final weight = initial weight \* g-weight. The 'g-weight' indicates the factor by which calibration has changed the initial weight.

## Population benchmarks

The following population benchmarks are used in the NZHS weighting:

- age group (0–4, 5–9, 10–14, 15–19, 20–24, 25–29, 30–34, 35–39, 40–44, 45–49, 50–54, 55–59, 60–64, 65–74, 75+ years) by sex (male, female) for all people
- age group (0–4, 5–9, 10–14, 15–29, 30–34, 35–39, 40–44, 45–49, 50–54, 55–64, 65+ years) by sex (male, female) for all Māori
- adult population by Pacific and non-Pacific peoples
- adult population by Asian and non-Asian
- total population by NZDep2013 quintile.

Age, sex, ethnicity (Māori, Pacific peoples, Asian, using self-identified total ethnicity) and socioeconomic position (NZDep2013) are included because these variables are related to many health conditions and to non-response, and they are a key output classification for the survey.

Quarterly calibration means that benchmarks are less detailed than would be possible if annual data sets were weighted. In particular, broader age groups are used for the Māori population benchmarks.

## **Benchmarks for the Māori population**

Quarterly benchmarks for the Māori population are constructed for the NZHS by projecting forward the annual (mid-year) population estimates for Māori released by Statistics New Zealand.

Using the Māori population estimates and total population estimates as at 30 June, the proportion of the total population who are Māori is calculated for each five-year age-by-sex group. Then these proportions are applied to quarterly total population estimates, by age and sex, for the subsequent four quarters.

For example, the proportion of each age-by-sex group who are Māori as at 30 June 2011 is used to construct estimates of the Māori population by age and sex in each of the quarters ending 30 September 2011, 31 December 2011, 31 March 2012 and 30 June 2012.

## **Benchmarks for the Pacific and Asian populations**

Quarterly benchmarks for the adult Pacific and Asian populations are derived from Statistics New Zealand's Household Labour Force Survey. This large national survey of 15,000 households per quarter achieves a very high response rate (close to 90 percent).

The Household Labour Force Survey publishes quarterly estimates of the working-age (aged 15 years and over) Pacific and Asian populations. From these estimates, the proportions of the adult population who are Pacific and Asian are obtained for each quarter. Some of the quarter-to-quarter variation in these proportions is smoothed out by applying a moving average over the quarterly figures. The final smoothed proportions are applied to the total adult benchmark for the corresponding quarter to give quarterly benchmarks for Pacific and Asian adults.

## **Benchmarks for the NZDep2013 quintiles**

Benchmarks for the quintiles of NZDep2013 are derived by dividing the latest total population figures (of all age groups) into five groups of equal size.

The calibration for the 2011/12 and 2012/13 surveys used benchmarks for the New Zealand Index of Deprivation 2006 (NZDep2006) based on 2006 Census data, while the surveys from 2013/14 onwards have used NZDep2013.

## **Calibrating software and bounding of weights**

The GREGWT SAS macro, developed by the Australian Bureau of Statistics, is used to calculate the calibrated weights. The input weights are the selection weights, first re-scaled to sum to the overall population benchmark. Final weights are constrained to be less than or equal to the smaller of 1625 and 2.5 times the input weight.

## **Jackknife replicate weights**

The NZHS uses the delete-a-group jackknife method (Kott 2001) to calculate standard errors for survey estimates.

One hundred jackknife replicate weights are produced for every respondent in the survey, in addition to the final calibrated weight. Each replicate weight corresponds to removing a group of PSUs from the sample and re-weighting the remaining sample using exactly the same approach as that used to construct the weights for the full sample, including calibration to the same population benchmarks.

For any weighted estimate calculated from the survey, 100 jackknife replicate estimates can also be calculated using the 100 jackknife weights. The standard error of the full sample estimate is based on the variation in the replicate estimates.

A number of statistical analysis packages, including SAS, Stata and R, can calculate standard errors using jackknife weights.

## **Weights for measurement data**

An additional set of estimation weights (and corresponding jackknife weights) has been created specifically for analysing the measurements collected from respondents as part of the core NZHS interview. Height and weight measurements are obtained from around 95 percent of eligible adult and 91 percent of eligible child respondents. As variables derived from height and weight are key outputs from the survey, it is useful to have this additional set of estimation weights to compensate for the additional non-response to these items.

The extra set of weights is calculated for the subset of respondents who have their height and weight measured. Creating these estimation weights follows exactly the same process as for the full sample. This consistent approach ensures that any bias due to lower participation in the measurement phase of the survey for particular demographic subgroups (such as age groups or ethnic groups) is accounted for in the final estimates for the survey.

These estimation weights are also used for analysis involving waist and blood pressure measurements. Waist and blood pressure measurements are obtained from almost all respondents who have had their height and weight measured.

## **Weights for alcohol consumption data**

In 2015/16, half of the adult respondents answered the same questions on alcohol consumption as the previous years, while the other half answered new questions that refer to a show-card about standard drinks (see also Section 4).

As expected, the two groups of respondents are very similar in terms of their age, sex, ethnicity and NZDep2013 profiles.

To further ensure that each half of the two sample groups accurately represents the New Zealand population, each group is re-weighted separately to match the same population benchmarks as for the full 2015/16 sample. These additional weights (and corresponding jackknife replicate weights) are only used for statistics derived from the alcohol consumption questions.

---

# Section 8: Analysis methods

## Estimating proportions, totals and means

Most statistics published in NZHS reports are proportions, totals or means, that is, survey estimates of:

- the proportion (or percentage) of people with a particular characteristic, such as a specific health condition, behaviour or outcome. (In epidemiology, the proportion of a population who have a disease or health condition at a specific period of time is called the prevalence of the disease or condition.)
- the total number of people with a particular characteristic
- the mean per person of some numeric quantity.

A description of the calculation method for each of these types of statistics follows. References to weights here mean the final calibrated weights discussed in Section 7.

### Adjusting for item non-response

Before calculating proportions, totals or means for a particular variable, an adjustment is made to the final weights to account for respondents who answered with 'don't know' or 'refused' to the relevant question or questions.

The adjustment increases the rating for the final weights of the respondents who answered the question, to represent the final weights of the respondents who answered 'don't know' or 'refused'. This is carried out within cells defined by sex and age group (10-year age groups for adults and five-year age groups for children), therefore making use of some information on what type of respondents are more likely to be item non-respondents to this variable. Then the item non-respondents can be safely left out of the calculation of proportions, totals or means for the variable.

The adjustment is most important for totals to ensure that item non-response does not lead to underestimating the number of people having a particular condition or behaviour. The effect will usually be very small for proportions and means; that is, proportions and means using the adjusted weights will be very similar to those using the final calibrated weights.

The adjustment is done 'on the fly' in the sense that the item-specific weights are created and used for estimating but are not kept on the survey data set.

### Calculating proportions

The proportion of the population who belong to a particular group (eg, the proportion of the population who have diabetes) is estimated by calculating the sum of the weights of the respondents in the group divided by the sum of the weights of all respondents.

The proportion of people in a population group who belong to a subgroup (eg, the proportion of Māori who have diabetes) is estimated by calculating the sum of the weights of the respondents in the subgroup (Māori who have diabetes) divided by the sum of the weights of the respondents in the population group (Māori).

## Calculating totals

Estimates of totals are given by calculating the sum, over all the respondents, of the weight multiplied by the variable of interest. For example, the estimate of the total number of people with diabetes in the whole population would be given by the sum, over all respondents, of the weight multiplied by a binary variable indicating which respondents have diabetes. This is equivalent to the sum of the weights of the respondents who have diabetes in the population.

## Calculating means

Estimates of population averages, such as the average number of visits to a GP, are determined by calculating the sum, over all respondents, of the weight multiplied by the variable of interest divided by the sum of the weights.

Sometimes the average within a group is of interest; for example, the average number of visits to a GP by males. The estimate is given by calculating the sum over respondents in the group, of the weight multiplied by the variable of interest, divided by the sum of the weights of the respondents in the group.

## Suppression of small sample sizes

Small samples can affect both the reliability and the confidentiality of results. Problems with reliability arise when the sample becomes too small to adequately represent the population from which it has been drawn. Problems with confidentiality can arise when it becomes possible to identify an individual, usually someone in a subgroup of the population within a small geographical area.

To ensure the survey data presented are reliable and the respondents' confidentiality is protected, data have only been presented when there are at least 30 people in the denominator (the population group being analysed). Care has been taken to ensure that no respondent can be identified in the results.

# Comparing population groups

## Age standardisation

NZHS reports mainly focus on presenting crude (unadjusted) estimates of the proportion or mean in the total population by age group (age-specific rates or means).

However, age is an important determinant of health, so population groups with different age structures (such as men and women, whose age structures differ due to women's longer life expectancy) may have different rates or means due to these age differences. This means that comparisons of crude rates or means over time and between groups may be misleading if the age structure differs between the groups being compared.

One approach to making more meaningful comparisons between groups is to compare age-specific rates or means. Alternatively it can be useful to summarise a set of age-specific rates or means for a group into a single age-independent measure. This is achieved by a process called **age standardisation**.

Age standardisation in NZHS reports is performed by **direct standardisation** using the World Health Organization (WHO) world population age distribution (Ahmad et al 2000). The direct method calculates an age-standardised rate, which is a weighted average of the age-specific rates, for each of the population groups to be compared. The weights applied represent the relative age distribution of the WHO population. This provides a single summary rate for each of the population groups being compared that reflects the rate that would have been expected if the group had had an age distribution identical to the WHO population.

The age-standardised rate (ASR) is given by:

$$ASR = \sum r_i (n_i / \sum n_i),$$

where  $n_i$  is the population in the  $i^{\text{th}}$  age group of the standard population and  $r_i$  is the rate in the  $i^{\text{th}}$  age group from the survey.

Age-standardised rates are provided in some tables to help make comparisons by sex, ethnic group and neighbourhood deprivation (NZDep2013) and between survey years.

Results for children are age-standardised to the population younger than 15 years, and results for adults are age-standardised to the population aged 15 years and over.

The same approach is used to age-standardised estimates of means.

### Adjusted rate ratios

NZHS reports also present comparisons between population groups as **rate ratios**; that is, as the ratio of the estimated proportions having the characteristic of interest in the two groups.

Rate ratios are used for comparing:

- men and women
- Māori and non-Māori (for the total population, men and women)
- Pacific and non-Pacific (for the total population, men and women)
- Asian and non-Asian (for the total population, men and women)
- people living in the most and least socioeconomically deprived areas.

In keeping with the use of total response ethnicity to present statistics by ethnic group, ethnic comparisons are presented such that Māori are compared with non-Māori, Pacific with non-Pacific and Asian with non-Asian. For this purpose, all respondents who identified as Māori are included in the Māori group; all other respondents are included in the non-Māori group. Similar groups are formed for Pacific and Asian ethnic groups.

Rate ratios can be interpreted in the following way.

- A value of 1 shows that there is no difference between the group of interest (eg, men) and the reference group (eg, women).
- A value higher than 1 shows that the proportion is higher for the group of interest than for the reference group.
- A value lower than 1 shows that the proportion is lower for the group of interest than for the reference group.

The rate ratios presented in NZHS reports are adjusted for differences in demographic factors between the groups being compared that may be influencing (confounding) the comparison. The adjustments are as follows.

- The sex comparison is adjusted for age.
- The ethnic comparisons are adjusted for age and sex.
- The deprivation comparison is adjusted for age, sex and ethnic group.

Adjusting for potential confounding factors makes comparisons more accurate and meaningful because the adjustment removes the effect of these confounding factors.

In the above comparisons, the comparison across neighbourhood deprivation is adjusted for ethnicity as well as age and sex. However, ethnic comparisons are adjusted for age and sex only; not for neighbourhood deprivation. This approach is used because ethnicity confounds the association between deprivation and health outcomes. By contrast, deprivation is only a mediator, not a confounder, of the association between ethnicity and health outcomes; that is, deprivation is on the path that links ethnicity to health outcomes. So, if ethnic comparisons were adjusted for deprivation, the analyses would not reflect the full independent effect of ethnicity but only that portion of the ethnic effect that is not mediated by the socioeconomic position of deprivation.

Adjusted rate ratios are calculated using the **predictive margins** approach of Korn and Graubard (1999), which Bieler et al (2010) call **model-adjusted risk ratios**. In this method:

- a logistic regression model is fitted to the data. The variable defining the groups to be compared, and the adjustment variables, are explanatory variables in the model
- the parameters of the fitted model are used to estimate the proportion having the characteristic of interest as if all the respondents belong to the group of interest (eg, are all male), but otherwise each respondent keeps their own values for the adjustment variables in the model (eg, age). That is, the proportion being estimated is for a hypothetical population of men who have the same age distribution as the full sample
- in the same way, the parameters of the fitted model are used to estimate the proportion having the characteristic of interest as if all the respondents belong to the comparison group of interest (eg, are all female), but otherwise each respondent keeps their own values for the adjustment variables in the model (eg, age). That is, the proportion being estimated is for a hypothetical population of women who have the same age distribution as the full sample
- once the model-adjusted proportions for the group of interest (eg, men) and the comparison group (eg, women) have been estimated in this way, their ratio can be calculated.

In the neighbourhood deprivation comparisons, the rate ratio refers to the **relative index of inequality** (Hayes and Barry 2002). This measure is used instead of simply comparing the most deprived quintile with the least deprived quintile. It is calculated by first using data from all quintiles to calculate a line of best fit (linear regression line), adjusted for age group, sex and ethnic group. The points on the regression line corresponding to the most and least deprived areas are used to calculate the rate ratio that is presented in the reports. This method has the advantage of using data from all the NZDep2013 quintiles to give an overall test for trend (gradient) by neighbourhood deprivation rather than only using the data from quintiles 1 and 5.

While total response ethnicity is used to report ethnic group statistics in the NZHS reports, a prioritised ethnicity variable is used when adjusting for ethnicity in the regression model underlying the relative index of inequality. Using prioritised ethnicity in the model simplifies the modelling process and gives results similar to including total response ethnicity variables in the model. The priority ordering of ethnic groups used is: Māori, Pacific peoples, Asian, European/Other.

## Confidence intervals and statistical tests

Ninety-five percent confidence intervals are used in NZHS reports to represent the sampling error associated with the statistics; that is, the uncertainty due to selecting a sample to estimate values for the entire population. A 95 percent confidence interval for a statistic is constructed in such a way that, under a hypothetical scenario where selecting the sample could be repeated many times, 95 percent of the confidence intervals constructed in this way would contain the true population value.

### Calculating confidence intervals

In most cases, confidence intervals presented in NZHS reports are calculated using the usual normal approximation. The upper and lower limits of the 95 percent confidence interval are found by:

$$\text{estimate} \pm 1.96 \times \text{standard error of the estimate}$$

However, confidence intervals based on the normal approximation sometimes do not work well when estimating small proportions. In these cases, the symmetrical behaviour of these normal confidence intervals can be unrealistic and can even lead to confidence intervals containing negative values.

The Korn and Graubard (1998) method is used to calculate more appropriate confidence intervals where:

- the prevalence estimate is less than 5 percent or greater than 95 percent
- the lower confidence interval limit from the normal approximation results in a value less than 0 percent
- the upper confidence interval limit from the normal approximation results in a value greater than 100 percent.

In any of these circumstances, the Korn and Graubard confidence intervals can and should be asymmetrical.

Confidence intervals for percentiles (eg, medians) are calculated using the Woodruff (1952) method.

### Tests for statistically significant differences

Some analysts assess whether two estimates differ significantly by seeing whether their confidence intervals overlap or not. This procedure is known to be overly conservative, resulting in a substantial degrading of statistical power, with some significant differences incorrectly assessed as insignificant.

When confidence intervals do not overlap, it can be concluded that the estimates differ significantly. However, when they do overlap, it is still possible that there is a significant difference. In this case, a *t*-test is used to correctly test the statistical significance of differences between NZHS estimates.

## Time trends

Where possible, the results of indicators presented in the current report are compared with the corresponding results from the previous years of the continuous NZHS (from 2011/12 onwards) and from the 2006/07 NZHS, to examine whether an indicator shows an increase or a decrease. This is referred to as 'time trends' in the annual report.

Testing the statistical significance of changes over time is based on age-standardised statistics.

# Section 9: New Zealand Health Survey 2015/16

This section provides some field-related data specific to the data collection and analysis of the NZHS in 2015/16 (year 5). The Appendix contains some information on a past NZHS carried out in 2006/07.

## 2015/16 NZHS modules

Table 3 outlines the NZHS module topics for 2015/16.

**Table 3: NZHS module topics, 2015/16**

Adult module topics	Child module topics
Tobacco use	Child development
Rheumatic fever (under 25 years)	Child food security
	Rheumatic fever

For details on the questionnaires for 2015/16, see the Ministry webpage: [www.health.govt.nz/publication/questionnaires-and-content-guide-2015-16-new-zealand-health-survey](http://www.health.govt.nz/publication/questionnaires-and-content-guide-2015-16-new-zealand-health-survey)

## Data collection

In year 5 of the continuous NZHS, 1 July 2015 to 30 June 2016, a total of 13,781 adults and 4721 children took part in the survey. Table 4 shows the number of respondents selected in each quarter of 2015/16.

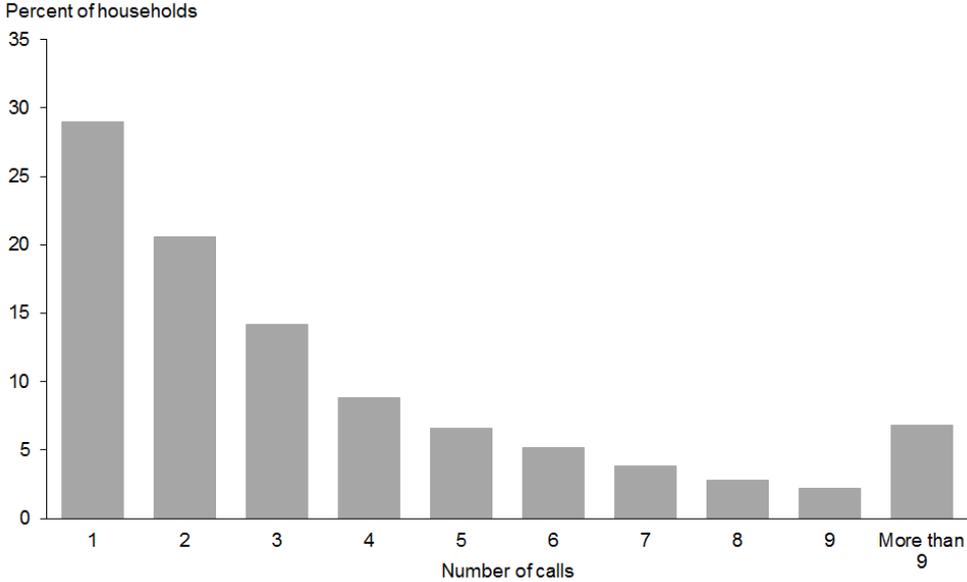

**Table 4: Number of survey respondents, by quarter, 2015/16**

	Adults		Children	
	Number	Percentage of total respondents	Number	Percentage of total respondents
Quarter 1 (July–September 2015)	3464	25	1237	26
Quarter 2 (October–December 2015)	3501	25	1198	26
Quarter 3 (January–March 2016)	3403	25	1141	24
Quarter 4 (April–June 2016)	3413	25	1145	24
<b>Total (July 2015–June 2016)</b>	<b>13,781</b>	<b>100</b>	<b>4721</b>	<b>100</b>

# Call pattern

The call pattern used in the NZHS, as described in Section 4, is an important part of achieving a high response rate. In 2015/16, surveyors followed a proven call approach, including visiting PSUs at different times and on different days depending on the area they were working in. For about 90 percent of households, the first (or only) interview took place within seven calls (Figure 1).

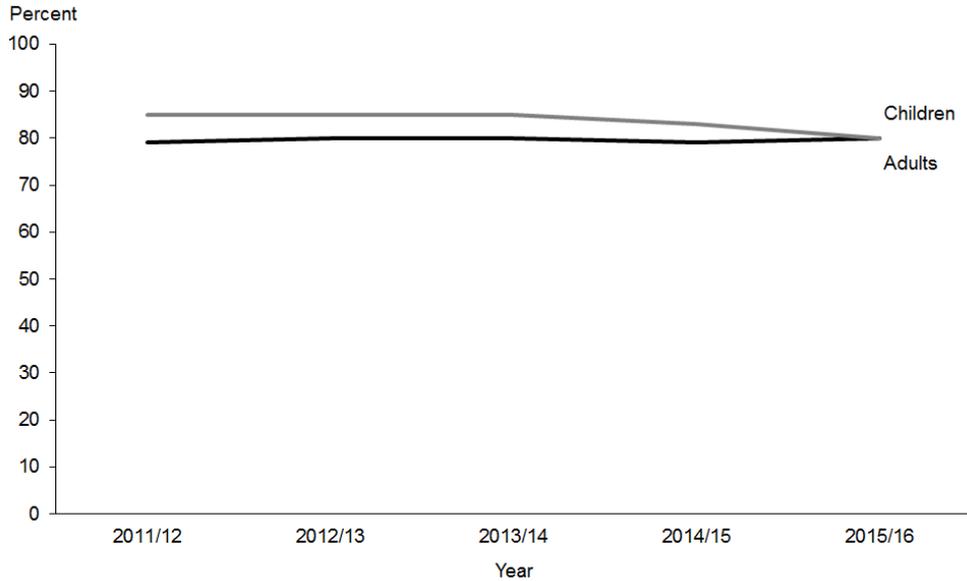

**Figure 1: Proportion of households agreeing to first interview, by number of calls, 2015/16**

# Response rates

The NZHS is well received by the public: the weighted response rate in 2015/16 was 80 percent for both adults and children. Figure 2 shows the time trend of response rates of adults and children from 2011/12 to the current survey year, 2015/16.

**Figure 2: Response rates (%) for adults and children, 2011/12–2015/16**

# Coverage rates

In 2015/16, the coverage rates were 67 percent for adults and 76 percent for children. Figure 3 shows the time trend of coverage rates of adults and children from 2011/12 to the current survey year, 2015/16.

**Figure 3: Coverage rates (%) for adults and children, 2011/12–2015/16**

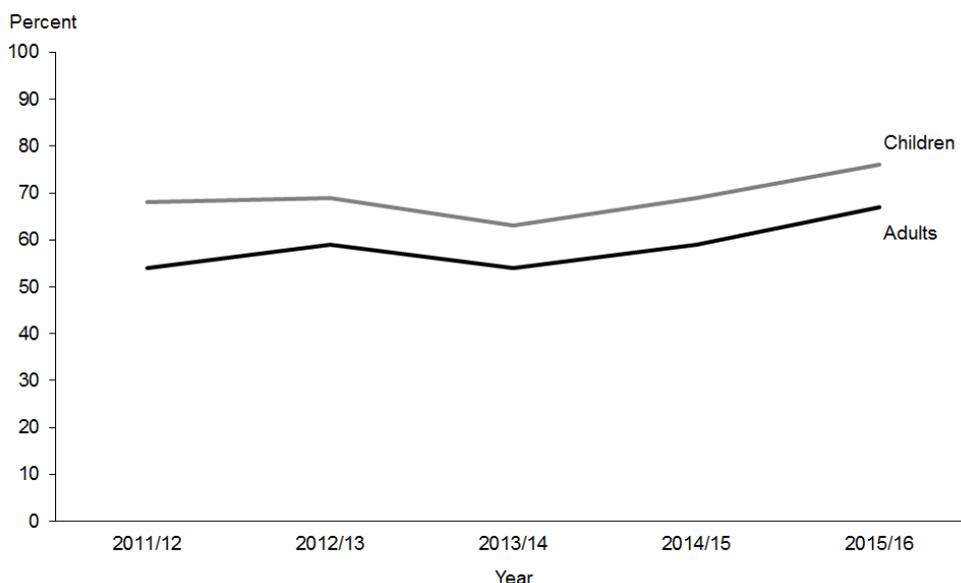

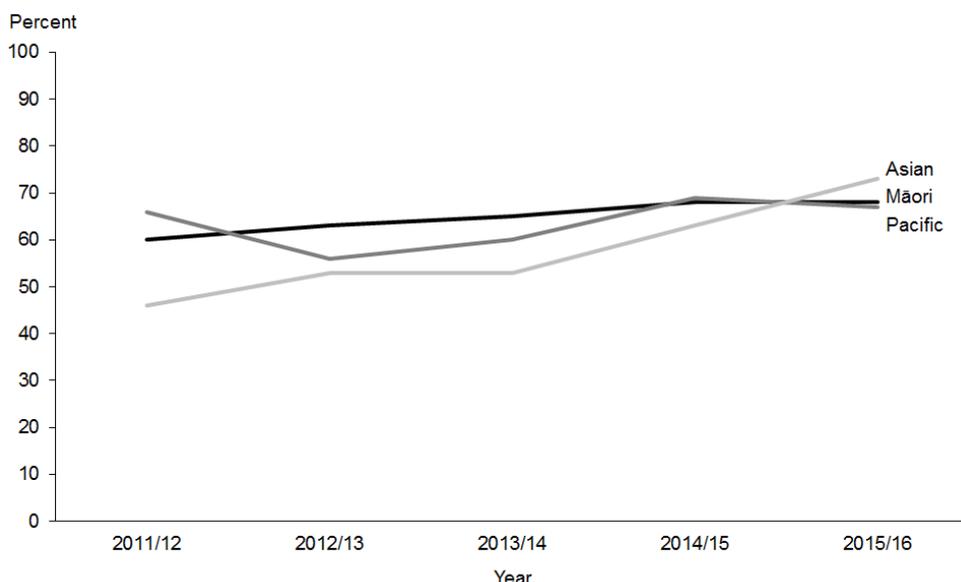

Figure 3 clearly shows that the coverage rates are high for children in all the years.

In 2015/16, the coverage rates were 68 percent for Māori, 67 percent for Pacific peoples and 73 percent for Asian peoples. Figure 4 shows the time trend of coverage rates for Māori, Pacific and Asian ethnic groups from 2011/12 to the current survey year, 2015/16.

**Figure 4: Coverage rates (%) for Māori, Pacific and Asian groups, 2011/12–2015/16**

As Figure 4 shows, the coverage rates are clearly improving for Asian people.

In 2015/16, the coverage rates for neighbourhood deprivation quintiles were 70 percent (Q1), 68 percent (Q2), 78 percent (Q3), 62 percent (Q4) and 64 percent (Q5). Figure 5 shows the time trend figures for Q1 to Q5 from 2011/12 to the current survey year, 2015/16.

**Figure 5: Coverage rates (%) by NZDep2013 quintiles, 2011/12–2015/16**

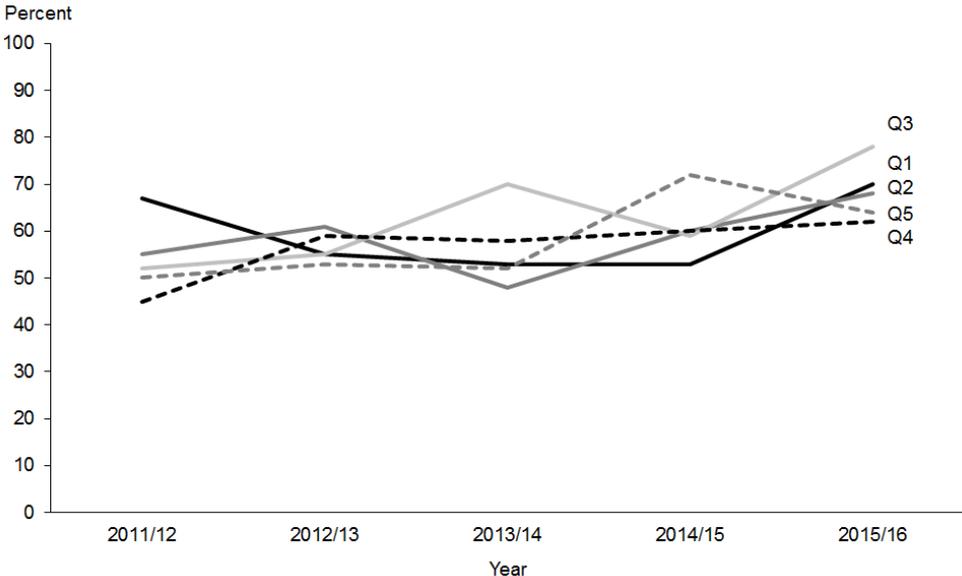

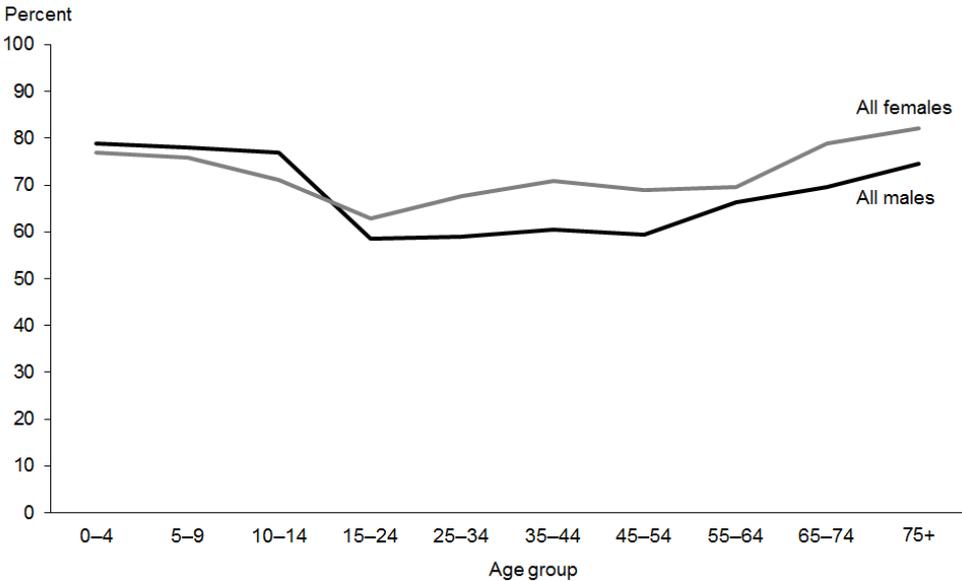

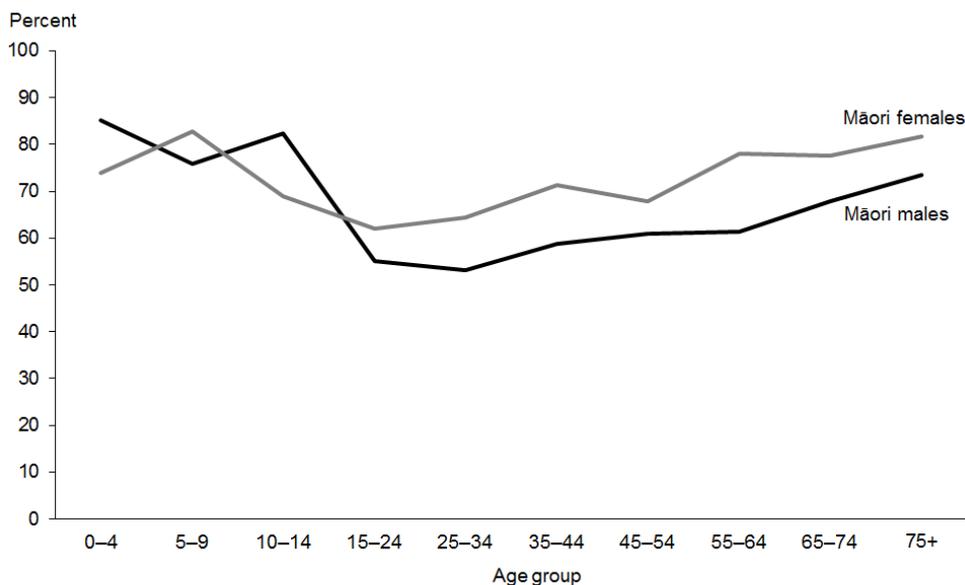

Figure 6 shows the coverage rates by age and sex for 2015/16. The pattern for Māori in Figure 7 is similar to the overall pattern shown in Figure 6.

**Figure 6: Coverage rates (%) for total population, by age group and sex, 2015/16**

**Figure 7: Coverage rates (%) for Māori, by age group and sex, 2015/16**

## Final weights

Section 7 has explained how the calibrated weights were calculated. Table 5 gives basic descriptive information on the final weights calculated for the 2015/16 survey.

The g-weights are the ratios of the final weights to the initial selection weights. The mean g-weight is approximately 1.7. This means the calibrated weights, which were calculated using population benchmark information, have changed the initial selection weight by an average factor of 1.7.

**Table 5: Final weights, 2015/16**

	Final weight
Minimum	19
Median	199
90th percentile	545
95th percentile	721
99th percentile	1117
Maximum	1625
Coefficient of variation (CV%)	82.9
Approximate design effect due to weighting (1 + CV <sup>2</sup> )	1.7

# Sample sizes

Tables 6–9 show the 2015/16 NZHS sample sizes and the total ‘usually resident’ population counts, by sex, ethnicity, age and NZDep2013 quintile.

**Table 6: Sample sizes and population counts for children and adults, by sex, 2015/16**

Population group	Sex	Interviews	Measurements* (2+ years)	Population count
Children (0–14 years)	Boys	2468	1697	468,187
	Girls	2253	1890	444,870
	<b>Total</b>	<b>4721</b>	<b>3587</b>	<b>913,057</b>
Adults (15 years and over)	Men	6003	5774	1,820,088
	Women	7778	7148	1,920,815
	<b>Total</b>	<b>13,781</b>	<b>12,922</b>	<b>3,740,903</b>

Note:

\* These numbers are based on the number of respondents with valid height and weight measurements, and they exclude 201 pregnant women, who are not eligible to be measured.

**Table 7: Sample sizes and population counts for children and adults, by ethnic group, 2015/16**

Ethnic group (total response)	Population group	Interviews	Measurements* (2+ years)	Population count
European/Other	Children	3181	2421	651,664
	Adults	10,435	9827	2,871,096
Māori	Children	1722	1288	234,943
	Adults	2770	2557	484,302
Pacific	Children	693	528	107,198
	Adults	838	785	223,000
Asian	Children	583	433	122,493
	Adults	1236	1158	450,250

Note:

\* These numbers are based on the number of respondents with valid height and weight measurements, and they exclude 201 pregnant women, who are not eligible to be measured.

**Table 8: Sample sizes and population counts, by age group, 2015/16**

Age group (years)	Interviews	Measurements* (2+ years)	Population count
0–4	1711	800	306,973
5–9	1486	1397	311,813
10–14	1524	1390	294,273
15–24	1630	1549	664,625
25–34	2261	2058	624,323
35–44	2219	2102	581,390
45–54	2135	2015	634,128
55–64	2168	2064	547,193
65–74	1854	1748	398,750
75 and over	1514	1386	290,495

Note:

\* These numbers are based on the number of respondents with valid height and weight measurements, and they exclude 201 pregnant women, who are not eligible to be measured.

**Table 9: Sample sizes and population counts, by NZDep2013 quintile, 2015/16**

NZDep2013 quintile	Population group	Interviews	Measurements* (2+ years)	Population count
Quintile 1 (least deprived neighbourhoods)	Children	633	520	175,365
	Adults	1876	1774	747,779
Quintile 2	Children	677	536	181,594
	Adults	2181	2066	758,370
Quintile 3	Children	975	714	163,222
	Adults	3030	2857	763,747
Quintile 4	Children	1005	761	181,665
	Adults	3150	2940	758,992
Quintile 5 (most deprived neighbourhoods)	Children	1431	1056	211,212
	Adults	3544	3285	712,014

Note:

\* These numbers are based on the number of respondents with valid height and weight measurements, and they exclude 201 pregnant women, who are not eligible to be measured.

---

# Section 10: Errors in previously published statistics

This section notifies NZHS users about errors in the statistics published in previous annual reports. These errors occurred as a result of independent events at different stages of the survey process, which are explained below.

Revisions to the data and statistics have been made as these errors have been uncovered. The size of the revisions has generally been very small, with the corrected statistics well within the confidence interval limits of the originally published statistics.

## Year 1, 2, 3 and 4 child nutrition indicators

The statistics for the two child nutrition indicators ‘solid food given before four months of age’ and ‘solid food given before six months of age’ in years 1–4 of the NZHS have been corrected.

There were two errors. Firstly, the ‘solid food given before four months of age’ indicator was supposed to report for children aged four months to four years, and ‘solid food given before six months of age’ was supposed to report for children aged six months to four years. However, the denominator of the ‘solid food given before four months of age’ indicator mistakenly included those children aged 0–4 months as well, and the ‘solid food given before six months of age’ indicator mistakenly included those children aged 0–6 months as well.

Secondly, there was a ‘Not applicable’ code in the questionnaire for those children not yet given solids. This ‘Not applicable’ category was treated as ‘missing’ and not properly considered in the calculation of the statistics for both indicators.

## Year 1, 2 and 3 estimation weights

The NZHS sample design involves selecting households systematically within meshblocks, using a skip algorithm. In years 1 to 3 of the survey (ie, 2011/12, 2012/13 and 2013/14), the skips used were different from those specified in the design. In particular, households in higher-growth meshblocks had a lower probability of selection than intended.

The estimation weights for respondents in years 1, 2 and 3 had previously been calculated using the intended probabilities of selection. The estimation weight of every respondent in years 1, 2 and 3 has now been recalculated to reflect each respondent’s actual probability of selection.

The revisions to the weights also took advantage of the availability of revised population estimates from Statistics New Zealand for the period between 2006 and 2013, which have been re-based to the 2013 Census.

The revisions to the weights mean that all year 1, 2 and 3 indicators in the year 4 report and accompanying tables may be different to those previously published.

An additional issue was that some respondents in the final quarter of year 3 were incorrectly assigned to an NZDep2013 quintile because they had been surveyed in a 2006 meshblock that was split by Statistics New Zealand into two or more new meshblocks in the 2013 meshblock pattern. These respondents have now been geo-coded to 2013 meshblocks and the correct NZDep2013 quintile used in both the calibration of the year 3 weights and all year 3 analyses by NZDep2013.

## **Year 1, 2 and 3 obesity cut-offs**

The statistics for underweight, healthy weight, overweight and obese classes in the 2011/12 and 2012/13 NZHS reports were based on the International Obesity TaskForce (IOTF) cut-off values for BMI published in Cole et al (2000, 2007).

In 2012, the IOTF slightly revised the cut-off values for those aged 2–18 years (Cole and Lobstein 2012). While the Indicator Interpretation Guide that accompanied the 2013/14 annual report included a table of the revised cut-off values, the 2013/14 statistics were mistakenly calculated using the old IOTF cut-off values.

The revised IOTF cut-off values have now been used to calculate the proportion of underweight, healthy weight, overweight and obese classes in all years of the continuous NZHS.

## **Year 2 height measurements**

After publishing the year 2 (2012/13) report, it was discovered that all height measurements for the year 2 respondents had been truncated to the next lowest centimetre. Heights are measured and recorded by CBG's surveyors to the nearest 0.1 centimetre, but an error had occurred in transferring the data to the Ministry.

Revised height measurements were used in all analyses of year 2 data for the year 3 (2013/14) annual report. Because respondents appeared to be shorter than they really were, the prevalence of obesity reported in year 2 was slightly overstated.

## **Surveyor dishonesty in year 1**

Just before publishing the year 1 (2011/12) report, dishonest practice was discovered in one surveyor's work in the areas of Hutt Valley and Capital & Coast DHBs. The affected data were removed and those households re-interviewed. The year 1 report was published without the data of the re-interviewed households.

Subsequently the re-interviewed records were included in the year 1 data set and the estimation weights recalculated. All year 1 statistics in the annual reports from year 2 onwards are based on the revised year 1 data set.

# Appendix: 2006/07 New Zealand Health Survey

To determine any changes in the prevalence of indicators over time, the annual report, *Annual Update of Key Results 2015/16*, shows results comparing the current NZHS with the NZHS survey conducted in 2006/07. This appendix gives a brief description of that 2006/07 survey.

## 2006/07 New Zealand Health Survey

The target population for the 2006/07 NZHS was the usually resident civilian population of all ages living in permanent private dwellings in New Zealand. An area-based frame of Statistics New Zealand meshblocks was used as the sample frame. Māori, Pacific and Asian peoples were oversampled.

Data were collected from October 2006 to the end of November 2007 using computer-assisted, face-to-face interviewing. The total response rate for the survey was 68 percent for adults and 71 percent for children. A total of 12,488 adults and 4921 children took part in the survey. The survey included 11,632 European/Other peoples, 5143 Māori, 1831 Pacific peoples and 2255 Asian peoples of all ages.

For full details on the methodology of the 2006/07 NZHS, see *A Portrait of Health: Key results of the 2006/07 New Zealand Health Survey* (Ministry of Health 2008).
